

## schema postcondition

[/Reference manual/Non-standard extensions to Z](#)

The schema postcondition operator is provided for symmetry with the schema precondition operator. However, Z does not permit a useful definition: this operator behaves as an identity function on schemas.

$$Expression = post, Expression;$$

The L<sup>A</sup>T<sub>E</sub>X mark-up of *post* is `\post`. The troff mark-up of *post* is `zpost`.
