

origin

[/Reference manual/Z-related commands/Browsing commands](#)

The *origin* command makes a selection to indicate from where the inspected formula originated.

When *origin* is applied to a goal in a proof (other than the original conjecture), or to a simplified form of a definition, it selects the formulae to which the command that generated the inspected goal or definition was applied. It also arranges for the initial selection in the menu of commands applicable to those formulae to be the name of that command.
