

postcondition

[/Reference manual/Z-related commands/Miscellaneous commands](#)

The *postcondition* command generates the postcondition of an operation expressed using the convention of a schema paragraph involving declarations with `?`, `!` or `'` decorations in their names. The whole schema paragraph must be inspected. The result, which is displayed in the left window, is rather less interesting than that of the *precondition* command, as it is not possible to disentangle a postcondition from the predicate of an operation expressed in this way, and so it is just a copy of the original operation, renamed.
